Abstract. As one of the most commonly employed UV-filters, 4-methylbenzylidene camphor (4-MBC) has been shown to accumulate in the environment and have endocrine disrupting activity. 4-MBC cannot be degraded completely by common methods in wastewater treatment plants. To prevent the environmental problems caused by 4-MBC from being more serious, finding effective method to degrade 4-MBC is essential. In this research, Fenton reaction and photo-Fenton was employed to degrade the 4-MBC. Orthogonal experimental design was employed to evaluate the influence of factors (Fe²⁺, H₂O₂, pH and reaction time) on the degradation of 4-MBC. The degradation rate reached to 66.01% in Fenton process and 96.71% in photo-Fenton process. UV light irradiation was also employed to degrade 4-MBC. After being irradiated by mercury lamp (300W) 90 min, the concentration of the 4-MBC reduced 85.4%, but most of them translated to the isomeride. Compared with the Fenton, photo-Fenton and UV light irradiation processes, we deduces that photo-Fenton can get the better degradation efficiency of 4-MBC, and, Fenton reagents and light irradiation are synergistic.

Keywords. 4-MBC, fenton reaction, light degradation, photo-fenton.

1 Introduction

Pharmaceutical and Personal Care Products (PPCPs) include drugs, hormones, fragrances, cosmetics, etc., which have attracted much public and scientific attention due to widespread contamination in aquatic environment. Among them, sunscreen cosmetic products have been used for more than 80 years [1], and its essential components are UV-filters. The main concern used to focus merely on their utility and efficiency as UV-filters, but, only very recently, concern has been raised regarding their path and their endocrine disrupting activity in the environment. UV-filters enter the aquatic environment either directly via wash-off from skin during swimming and bathing activities, or indirectly via wastewater from wastewater treatment plants (WWTPs) [2]. Due to the high lipophilicity and relative stability against biotic degradation, UV-filters have been shown to accumulate in the food chain by bioaccumulation and potential biomagnification [3]. Studies have proved that some organic UV-filters exhibit endocrine disrupting activity [4, 5].

4-methylbenzylidene camphor (4-MBC) is an organic camphor derivative which has the ability to protect the skin against UV-B radiation, and it is one of the most commonly employed UV-filters [6]. However, it has been shown to accumulate in the environment. The concentration of 4-MBC can reach to 113±7 ng-L⁻¹ in the surface water around Majorca Island [7]. It also can be detected in the muscle tissue of fish from seven small Swiss Rivers, all receiving inputs from wastewater treatment plants [8]. And even in tap water, 4-MBC also exist and the concentration can reach to 35 ng-L⁻¹[9]. 4-MBC has also been proved to have endocrine disrupting activity. Researches demonstrate that it can affect the rats' development of reproductive organs [10], the number of embryos of Pantipodarum [11], and accelerate the cell proliferation in MCF-7 breast cancer cells [12].

Studies reveal that UV-filters cannot be degraded completely in WWTPs, and 4-MBC is the most prevalent UV filter detected in treated wastewater[13]. To prevent the environmental problems caused by 4-MBC from being more serious, finding effective method to degrade 4-MBC is essential. Fenton and photo-fenton, which are the commonly used methods in degrading organic pollutants, were employed to degrade 4-MBC in the research. orthogonal experiments were employed to verify the interaction effects of factors responsible (Fe²⁺, H₂O₂, pH and reaction time) on the degradation efficiency of 4-MBC. UV light irradiation was also explored. The degradation efficiency of Fenton, photo-Fenton and UV light irradiation were compared. The degradation efficiency was determined by HPLC (High Performance Liquid Chromatography). To the best of our knowledge, this is the first time todo the work.

2 Materials and Methods

2.1 Materials and Instruments

4-MBC was purchased from Brilliance Biochemical Company (Beijing, China) and the purity was higher than 99%. Acetonitrile (HPLC grade) was obtained from Damao Chemical Regent Factory (Tianjin, China). Analytically pure grade H\textsubscript{2}O\textsubscript{2} (30%), FeSO\textsubscript{4} \cdot 7H\textsubscript{2}O, NaOH used in the experiments were purchased from Damao Chemical Regent Factory (Tianjin, China) and H\textsubscript{2}SO\textsubscript{4} was from Tieta (Laiyang, China). All reagents were used without further purification. High-purity water (18.2 MΩ cm) was used throughout all experiments, and it was prepared on an ELGA purelab flex system (ELGA, Veolia Water, Marlow, UK).

Photochemical reactor (BL-GHX) was manufactured by Bilon Instrument Company (Shanghai, China). It was mainly comprised of light source, cylindrical reactor, magnetic stirrer and circulating cooling system. Mercury lamp was employed (300W) as light source and the lamp was vertically located in the center of the reactor. Orbital shaker (HV-4) used in the experiments was manufactured by guohua, (Changzhou, China). A Leici PHS-3C pH meter (Shanghai Leici Corporation, Shanghai, China) was used for pH measurements. The LC system comprised a Shimadzu SPD-20A UV detector, and a LC-20AT high-pressure solvent delivery pump with a 20 mL sample loop injector. The column used in our experiments was Anasil AQ-C18 (25 cm \times 4.6mm, 5μm).

2.2 Fenton process

In Fenton process, the vital factors are the initial concentration of the 4-MBC, the dosages of H\textsubscript{2}O\textsubscript{2}, pH value, amount of Fe\textsuperscript{2+}, reaction time. For the aim of the research is to assess the ability of Fenton in degrading 4-MBC, we fixed the initial concentration of 4-MBC and chose factors (Fe\textsuperscript{2+}, H\textsubscript{2}O\textsubscript{2}, pH and reaction time) as variables and evaluate their effect on degradation. Orthogonal experimental design was employed to optimize the reaction conditions of Fenton process. The Fenton reaction was carried out in a conical flask (200 mL). The initial concentration of 4-MBC aqueous was 10 mg/L and the volume of reaction solutions was 50 mL. The addition of H\textsubscript{2}O\textsubscript{2} and FeSO\textsubscript{4} \cdot 7H\textsubscript{2}O were at beginning. The pH value, initial concentrations of H\textsubscript{2}O\textsubscript{2} and FeSO\textsubscript{4} \cdot 7H\textsubscript{2}O were listed in Table 1. All the reaction solutions were well mixed and were vibrated by orbital shaker during the reaction. The whole Fenton process was working in darkness.

2.3 UV light irradiation

In UV light irradiation process, the vital factors are reaction time, light source and the initial concentration of 4-MBC. For the feature of absorbing UV light, mercury lamp was employ as the light source. Same to the Fenton process, the concentration of 4-MBC was not thought about. Just reaction time was taken as the factor. Photochemical reactor was employed in UV light irradiation processes. Degradation was performed on 200 mL 4-MBC aqueous. During the reaction, about 3 mL samples were took out at 30 min, 45 min, 60 min, 75 min and 90 min respectively.

2.4 Photo-Fenton Process

The major factors affecting the photo-Fenton process are the initial concentration of the 4-MBC, the dosages of H\textsubscript{2}O\textsubscript{2}, pH value, amount of Fe\textsuperscript{2+}, reaction time and the light source \cite{14}. According to Fenton and irradiation processes, we employed mercury lamp as the light source, fixed the initial concentration of 4-MBC and chose factors (Fe\textsuperscript{2+}, H\textsubscript{2}O\textsubscript{2}, pH and reaction time) as variables and evaluate their effect on degradation. Orthogonal experimental design was also employed to optimize the reaction conditions of photo-Fenton process. The factors and levels of the orthogonal experimental design were listed in Table 2. The addition of H\textsubscript{2}O\textsubscript{2} and FeSO\textsubscript{4} \cdot 7H\textsubscript{2}O were at beginning. The whole photo-Fenton process was carried out in the photochemical reactor. The initial concentration of 4-MBC aqueous was 10 mg/L. Degradation of each group was performed on 200 mL 4-MBC aqueous.

2.5 Analytical procedures

The concentration of 4-MBC in solution was detected by HPLC (High Performance Liquid Chromatography). Before being injected into the LC system, the solution samples were passed through 0.45 μm Nylon, polyamide membranes filters. The column used in our experiments was Anasil AQ-C18 (25 cm × 4.6 mm I.D. 5 μm packing). The column temperature was maintained at 30 ℃. Water/acetonitrile (20/80%, v/v) was used for the isocratic elution of the analyte. Spectrum identification was performed at the wavelength of 300 nm [15].

3 Results

3.1 Fenton process

From Table 3, it could be saw that the highest degradation reached to 66.01%. It could be deduced from the range value (R) in table 3: RB > RA > RD > RC. It meant that the dosage of \text{H}_2\text{O}_2 \text{ had the greatest effect on the degradation of 4-MBC in Fenton process, then followed by the portion of } \text{H}_2\text{O}_2 \text{ and Fe}^{2+}, \text{ but the reaction time had the less effect. And the K value revealed that when the portion of } \text{H}_2\text{O}_2 \text{ and Fe}^{2+} \text{ was 1:5, the dosage of } \text{H}_2\text{O}_2 \text{ was 1 mL, the reaction time was 30 min and the pH value was 3, the highest degradation could be reached. Fig. 1 illustrated the trend curves of different level vs different factor.}

3.2 Irradiation process

When mercury lamp was used alone to degrading the 4-MBC, the degradation of 4-MBC at different time was tested (Fig.2). It revealed that as time growing, the concentration of 4-MBC was decreasing. After irradiating 90 min, the concentration decreased 85.4%.

Fig.2. The effect of irradiation time on the degradation of 4-MBC. pH=7, C₀(4-MB) = 10mg/L.

### 3.3 Photo-Fenton process

The reaction condition and the degradation of each group were listed in Table 4. It could be deduced from the range value R in table 4: RB>RC>RD>RA. It meant that the dosage of H₂O₂ had the greatest effect on the degradation of 4-MBC in photo-Fenton process, then followed by the reaction time, but the portion of H₂O₂ and Fe²⁺ had the less effect. The degradation of 4-MBC varied between 76.77% and 96.71%. The K value revealed that when the portion of H₂O₂ and Fe²⁺ was 5: 1, the dosage of H₂O₂ was 0.1mL, the reaction time was 60 min and the pH value was 3, the highest degradation could be reached.
4 Discussion

Figure 1a and Figure 1b revealed that in Fenton process, along with the increase of the dosage of FeSO4 • 7H2O and H2O2, the degradation was increase. More FeSO4 • 7H2O and H2O2 were not employed, for the dilution effect caused by H2O2 and the economy issue. The degradation of 4-MBC varied between 18.01% and 66.01% in Fenton process. Even the highest degradation was lower than the photo-Fenton process's lowest degradation. It was known that the Fenton and photo-Fenton reactions are mostly based on the production of hydroxyl radical HO• in water. As it is classically described, hydroxyl radicals are produced in this technique by the decomposition of hydrogen peroxide when reacting with ferrous ions (reaction 1) [16]. Irradiation with sunlight, an artificial light source of wavelength 180-400nm, or even in the visible spectra [17] increases the rate of contaminant degradation mainly by stimulating the Fe3+ to Fe2+ reduction (reaction 2) [16]. Thus, the degradation of 4-MBC in photo-Fenton reaction is higher than Fenton reaction.

\[ H_2O_2 + Fe^{3+} \rightarrow Fe^{2+} + HO^- + HO^- \]  
\[ Fe^{3+} + H_2O \rightarrow Fe^{2+} + H^+ + HO^- \]  

It was known that 4-MBC could exist as a (Z) or (E)-isomer due to the exocyclic carbon–carbon (styrene) double bond, and 4-MBC was shown to consist entirely of (E)- in commercial sunscreen products [18]. But when exposure to light, (E)-isomer is isomerized reversibly to (Z)-isomer [19]. Thus, although the degradation could reach to 85.41% after irradiating 90 min, we thought the light promoted the 4-MBC to translate to its isomeride, but did not decompose it.
Figure 3 illustrated the trend curves of different factors in photo-Fenton process. And Fig.3a revealed that the degradation rate of 4-MBC decreased firstly, and then increased. Comparing to Fig.1a, we speculated that the ferric ion weakened the irradiancy. The efficiency of Fenton reaction on degradation was better than the effect of irradiation when the concentration of ferric ion was high. Then the degradation decreased, because along with the decrease of the ferric ion, the efficiency of the Fenton reaction was also decreased and the irradiation process could not work well for the weakening of the irradiation by ferric ion. With the continuous decrease of the ferric iron, the degradation increased. We thought that irradiation make a significant contribution to the degradation in this stage. Fig.3b revealed that along with the increase of the H2O2, the degradation was decreased. It was because that the H2O2 also could consume the hydrogen radicals, which was achieved by reaction (3) [20]. Thus the degradation of 4-MBC would decrease when the amount of H2O2 increase. Fig.3c indicated that the degradation increased with the time going and Figure 3d indicated that the degradation decreased with the pH value increasing.

\[
\cdot OH + H_2O_2 \rightarrow O_2^- + H_2O
\]  

(3)

5 Conclusion

When the initial concentration of 4-MBC was 10 mg/L, and the dosage of the Fenton regents (Fe²⁺,H₂O₂) were at the same level, degradation efficiency of 4-MBC in photo-Fenton process was better than Fenton process and the best degradation reached to 96.71% and 66.01% respectively. In UV light irradiation process, the concentration of 4-MBC decreased 85.4%. But most of them translated to the isomeride. Compared with the Fenton and photo-Fenton process, we deduced that Fenton reagents and light irradiation were synergistic.
